<b>Purchase Order Total</b>					<b>\$3,082.80</b>

# Purchase Order - Attribute Analysis

ATTRIBUTE	TYPE	LEN- GTH	DESCRIPTION
PO-NO	N	3	Unique purchase order (PO) number. Many parts can be ordered in one PO
PO-DATE	D	8	DDMMYYYY date when PO written
EMP-CODE	C	2	Unique code of employee who wrote the PO
SUPP-NO	N	3	Unique number assigned to supplier
SUPP-NAME	C	20	Supplier name
PART-NO	N	2	Unique number assigned to each part
PART-DESC	C	10	Part description
PART-QTY	N	2	Quantity of parts ordered in given PO

**Key** PO-NO

# Normalisation

# Objectives

- Explain the reasons for normalising data
- Describe the process of normalisation
- Describe the benefits of normalisation

# Normalisation

Is derivation of data as a set of

**Non-Redundant,**

**Consistent and**

**Inter-Dependent Relations**

# Normalisation

- Normalisation is a set of data design standards.
- It is a process of decomposing unsatisfactory relations into smaller relations.
- Like entity–relationship modelling were developed as part of database theory.

# Why Normalisation?

- Understand the meaning of data
- Understand inter-relationship and inter-dependence of data
- Minimise data redundancy and inconsistency
- Prevent data update problems

# Normalisation - Advantages

Reduction of data redundancy within tables:

- Reduce data storage space
- Reduce inconsistency of data
- Reduce update cost
- Remove many-to-many relationship
- Improve flexibility of the system

# Normalisation - Disadvantages

Reduction in efficiency of certain data retrieval as relations may be joined during retrieval.

- Increase join
- Increase use of indexes: storage (keys)
- Increase complexity of the system

# Normal Forms

A state of a relation that results from applying simple rules regarding functional dependencies (or relationships between attributes) to that relation.

0NF multi-valued attributes exists

1NF any multi-valued attributes have been removed

2NF any partial functional dependencies have been removed

3NF any transitive dependencies have been removed

# Normal Forms cont'd

- BCNF any remaining anomalies that result from functional dependencies have been removed
- 4NF any multi-valued dependencies have been removed
- 5NF any remaining anomalies have been removed

# Functional Dependencies and Keys

**Functional dependency:** A constraint between two attributes or two sets of attributes

The functional dependency of B on A is represented by an arrow:  **$A \rightarrow B$**

e.g.

NID (SSN)  $\rightarrow$  Name, Address, Birth date

VID  $\rightarrow$  Make, Model, Colour

ISBN  $\rightarrow$  Title, First Author

# Functional Dependencies and Keys

## **Functional dependency (*definition*)**

For any relation R (*e.g. book*), attribute B (*e.g. title*) is functionally dependent on attributes A (*e.g. ISBN*), if for every valid instance of A (*e.g. 981-235-996-6*), that value of A uniquely determines the value of B (*e.g. Modern Database Management*)

# Input for the Normalisation Process

## Database Design process (phase 1)

*data requirements and data analysis*

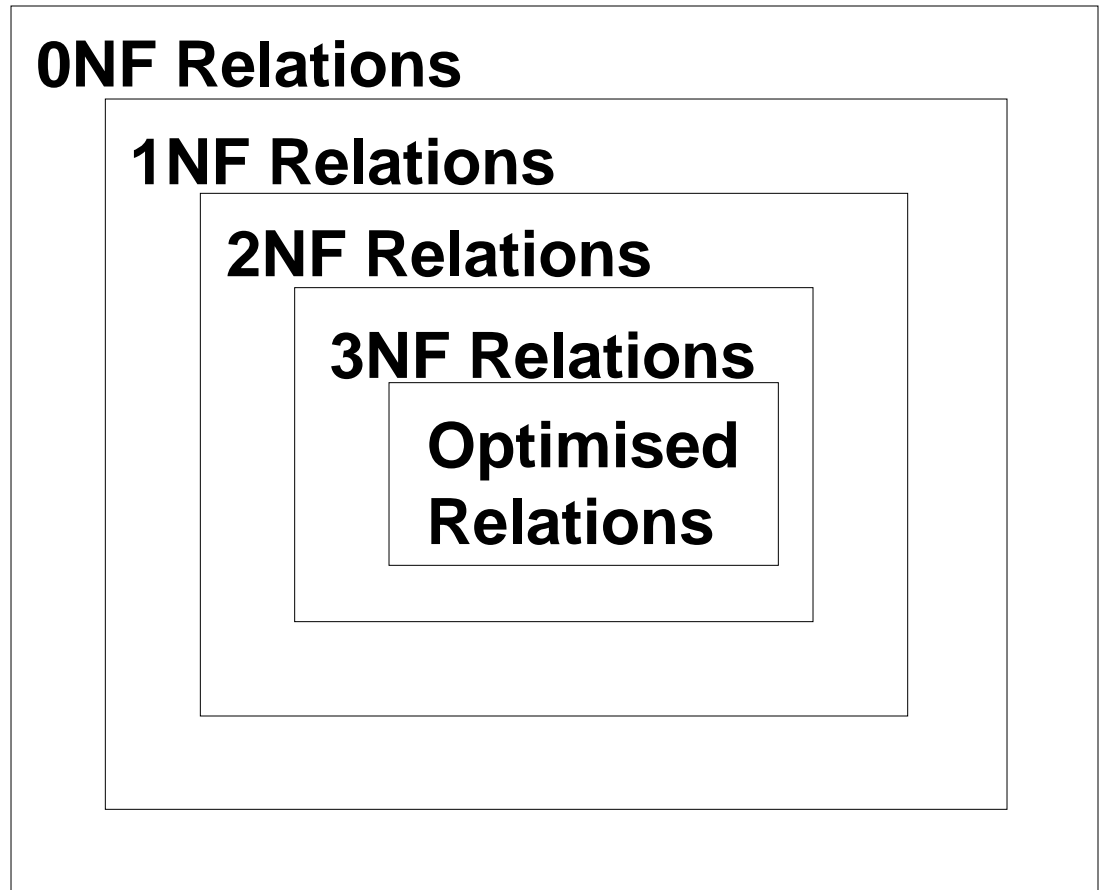

**entity types** (*e.g. Supplier, Order*)

**attributes** describing each entity type with its meaning (*e.g. supplier name and part name*)

**attributes relationships** to other attributes.  
(*e.g. supplier no of Supplier to supplier no of purchase Order*)

# Normalisation Process

Apply a set of normalisation rules to all the attributes of the entity types identified in the data requirement step.

# Output of the Normalisation Process

- A list of normalised entity types in at least third normal form (3NF), such that all non-key attributes of each entity type fully depend on the whole key and nothing but the key

# First Normal Form - 1NF

A relation is in First Normal Form (1NF) if **ALL** its attributes are **ATOMIC**.

i.e. If there are no repeating groups.

If each attribute is a primitive.

e.g. integer, real number, character string,  
but not lists or sets

non-decomposable data item

single-value

# Purchase Order Relation in 0NF

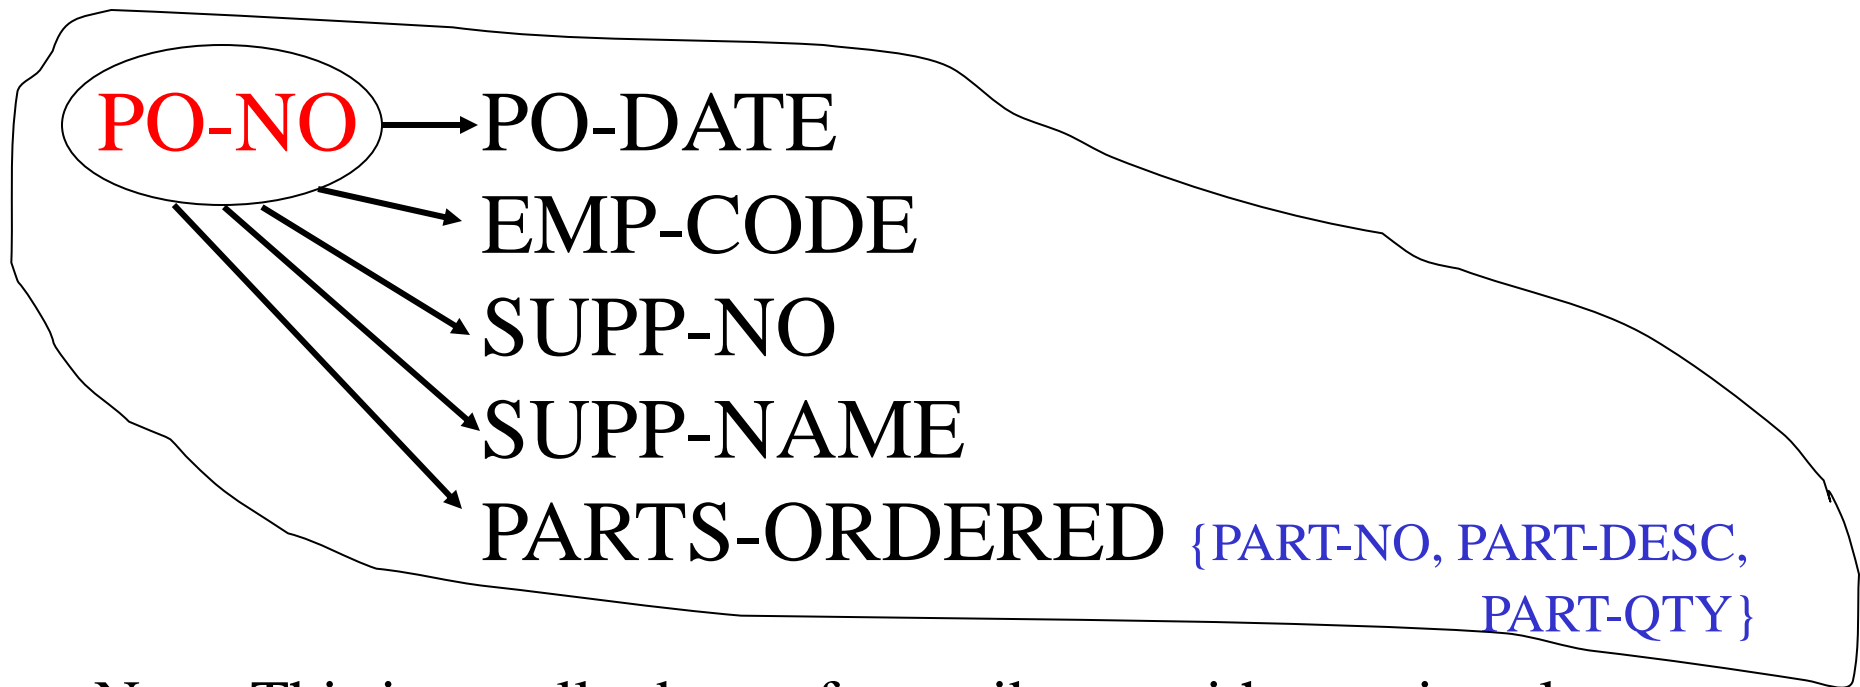

PO( PO-NO, PO-DATE, EMP-CODE, SUPP-NO,  
SUPP-NAME, **PARTS-ORDERED**{PART-  
NO, PART-DESC, PART-QTY})

Within a single purchase order we could find several part numbers, part descriptions and part quantities. Hence, parts ordered can be decomposed.

# Purchase Order Relation in 0NF

## Functional Dependency diagram

**PO-NO** → PO-DATE, EMP-CODE, SUPP-NO, SUPP-NAME, PARTS-ORDERED

Note: This is usually drawn for attributes with atomic values

# Purchase Order Relation in 0NF

116	04012001	S1	100	LM Centre	P8	Fuse	21 2

# First Normal Form - 1NF

- 1NF deals with the *shape* of a record type
- All occurrences of a record type must contain the same number of fields
- A relational schema is at least in 1NF

# 1NF - Actions Required

- 1) Examine for repeat groups of data
- 2) Remove repeat groups from relation
- 3) Create new relation(s) to include repeated data
- 4) Include key of the 0NF to the new relation(s)
- 5) Determine key of the new relation(s)

## Functional Dependency diagram

$PO\text{-}NO \rightarrow PO\text{-}DATE, EMP\text{-}CODE, SUPP\text{-}NO, SUPP\text{-}NAME$

$PO\text{-}NO, PART\text{-}NO \rightarrow PART\text{-}DESC, PART\text{-}QTY$

# Problems - 1NF

## 1. INSERT PROBLEM

cannot know available parts until an order is placed  
(e.g. P4 is bush)

## 2. DELETE PROBLEM

lose information of part P7 if we cancel purchase  
order 115 (i.e. Delete PO-PART for Part No P7)

## 3. UPDATE PROBLEM:

to change description of Part P3 we need to change  
every tuple in PO-PART containing Part No P3

# Second Normal Form - 2NF

A relation is in 2NF if it is in 1NF and every non-key attribute is dependent on the whole key

i.e. Is not dependent on part of the key only.

# PO-PART Relation (Parts Ordered) in 1NF

PO-PART( PO-NO, PART-NO, PART-DESC,  
PART-QTY) 

Part Description is depended only on Part No, which is part of the key of PO-PART.

# Parts Ordered Relation in 1NF

PO-PART( PO-NO, PART-NO, PART-DESC, PART-QTY)

<b>PO- No</b>	<b>PART- No</b>	<b>PART- DESC</b>	<b>PART- QTY</b>
111	P1	Nut	10
111	P2	Bolt	5
111	P3	Nail	3
111	P5	Screw	6

112	P5	Screw	1
113	P1	Nut	3
113	P3	Nail	4
114	P6	Plug	5
115	P7	Pin	8
116	P8	Fuse	2

# Second Normal Form - 2NF

Deals with the relationship between non-key and key fields

A non-key field cannot be a fact about a subset of a key

It is relevant when the key is composite, i.e. consists of several fields

# 2NF - Actions Required

If entity has a concatenated key

- 1) Check each attribute against the whole key
- 2) Remove attribute and partial key to new relation
- 3) Optimise relations - consider combining tables that have identical primary keys

# Parts Ordered Relation in 1NF

$PART\text{-}NO \rightarrow PART\text{-}DESC$

# Problems - 2NF

## 1. INSERT PROBLEM

cannot know available suppliers until an order is placed (e.g. 200 is hardware stores)

## 2. DELETE PROBLEM

lose information of supplier 100 if we cancel purchase order 116 (i.e. Delete PO for Supplier No 100)

## 3. UPDATE PROBLEM

to change name of Supplier 222 we need to change every tuple in PO containing Supplier No 222

# Third Normal Form - 3NF

A relation is in 3NF if it is in 2NF and each non-key attribute is only dependent on the whole key, and not dependent on any non-key attribute.

i.e. no transitive dependencies

# PO Relation in 2NF

PO( **PO-NO**, PO-DATE, EMP-CODE,  
**SUPP-NO**, **SUPP-NAME**)

Supplier name is a non-key field depended on another non-key field (i.e. the supplier no) in addition to be depended on the key purchase order no

# Purchase Order Relation in 2NF

PO( PO-NO, PO-DATE, EMP-CODE, SUPP-NO, SUPP-NAME)

# Normalised Relations

It is sufficient to show only the relations using only the following notations, i.e. not necessary to show the tables with data elements.

PO( PO-NO, PO-DATE, EMP-CODE, SUPP-NO)

PART( PART-NO, PART-DESC)

SUPPLIER( SUPP-NO, SUPP-NAME)

PO-PART( PO-NO, PART-NO, PART-QTY)

# Purchase Order Relation in 3NF

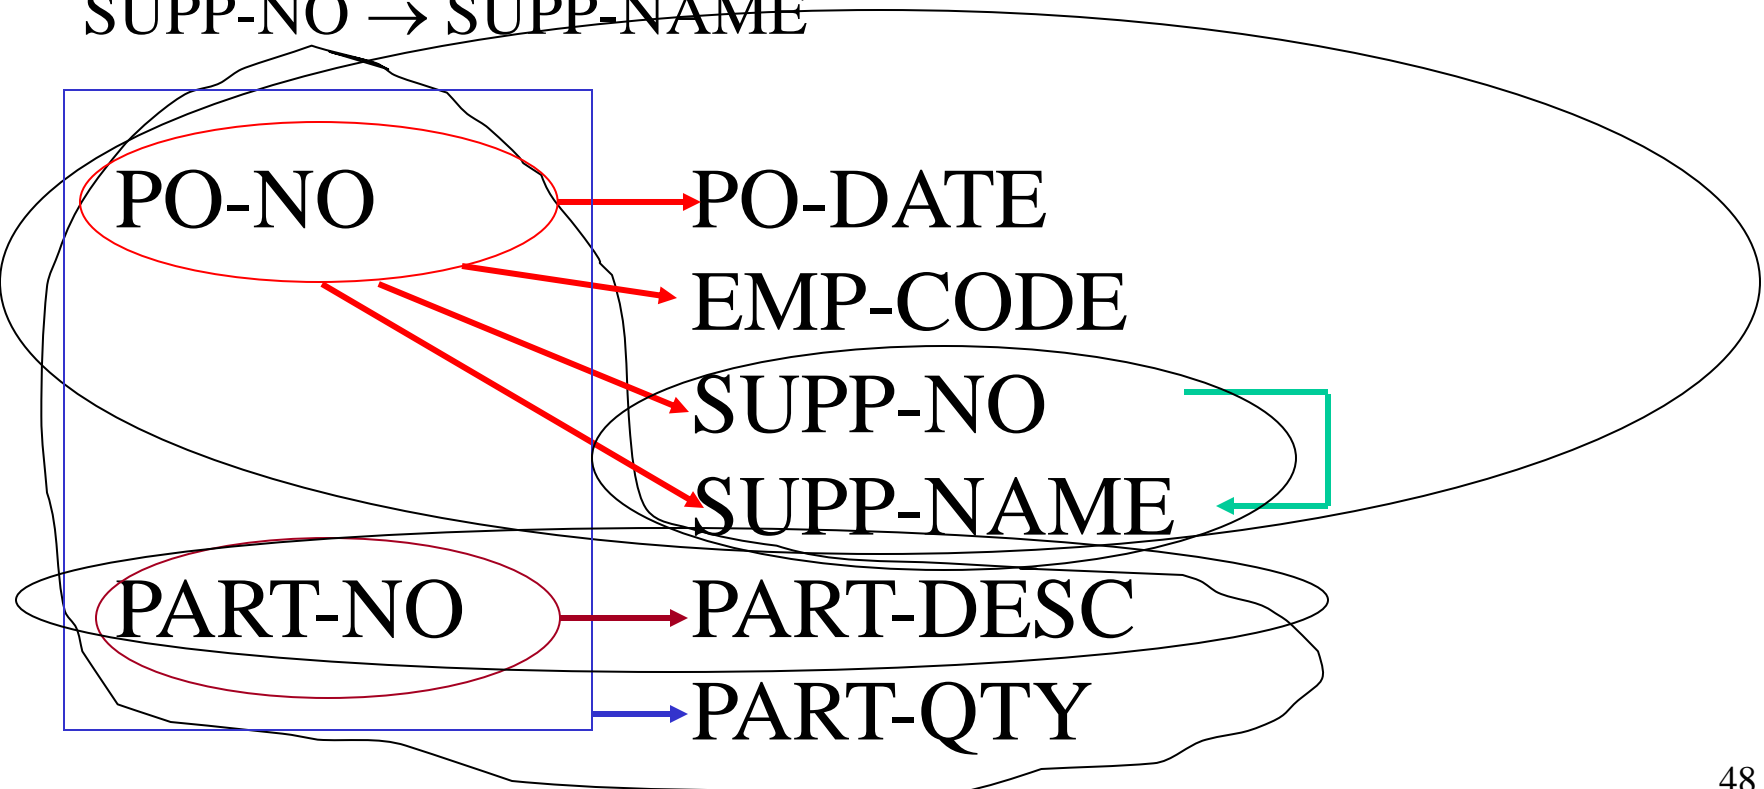

## Functional Dependency diagram

$PO\text{-}NO \rightarrow PO\text{-}DATE, EMP\text{-}CODE, SUPP\text{-}NO$

$PO\text{-}NO, PART\text{-}NO \rightarrow PART\text{-}QTY$

$PART\text{-}NO \rightarrow PART\text{-}DESC$

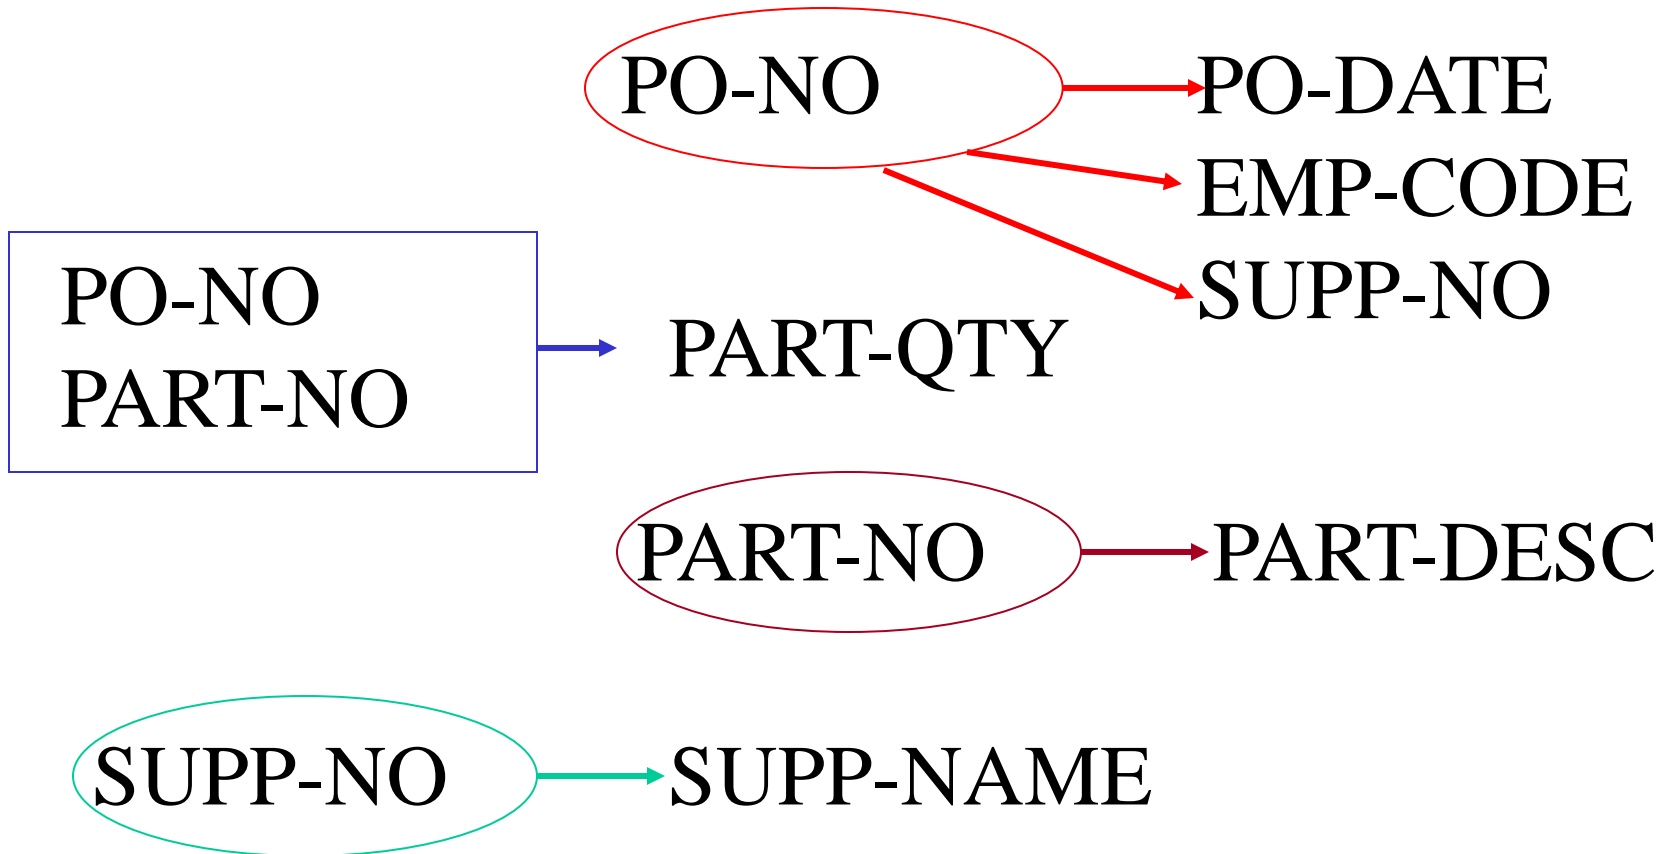

$SUPP\text{-}NO \rightarrow SUPP\text{-}NAME$

# Functional Dependency diagram ...

Draw one diagram showing **all** dependencies as in previous slide or a collection of diagrams as shown below

# Optimisation

combining tables that have identical primary keys

Table-1(K1, K2, K3, DE1, DE2, DE3)

Table-2(K1, K3, K2, DE2, DE4, DE5)

Table-3(K1, K2, K3, DE1, DE2, DE3, DE4, DE5)

- K is a Key-element and DE is a Data-element
- Key sequence is not important
- Don't lose data elements

# Optimisation ...

combining tables that have identical primary keys

STUDENT(NID, Name, Course)

EMP(NID, Name, Designation)

STU-EMP(NID, Name, Course, Designation)

If a student can become an employee, and vice-versa, and also be both at a given time, we can reduce duplication by **COMBINING** the tables

# Optimisation ...

## Two Approaches

1. Optimise at the end of each normalization step
2. Optimise after 3NF

- Recommend a combination of both
- Combine simple key relations with few data elements after each step
- Leave other more complex key relations until after 3NF
- Reason for this being that more re-working is necessary if optimise everything, then subsequent revisions or errors correction required.

# Generalisation

- This process reduces redundancy and is done in addition to Normalisation
- Examine root tables, i.e. those that represent entity types directly, and their repeating groups (after 1NF).  
e.g. STUDENT, EMPLOYEE, etc.
- Reduce data elements to their Generic Names  
e.g. INSTRUCTOR-NAME becomes NAME,  
STUDENT-NAME becomes NAME,  
ISTRUCTOR-NUMBER becomes NUMBER,  
STUDENT-NUMBER becomes NUMBER,

# Generalisation ...

reduces redundancy

STUDENT(NID, Stu-Name, Course)

EMP(NID, Emp-Name, Designation)

STU-EMP(NID, Stu-Name, Emp-Name, Course,  
Designation)

STU-EMP(NID, Name, Course, Designation)

# Generalisation ...

- Hence if any tables have the same generic key and are occurrences of the same entity type (as opposed to different entity-types) we:
  - COMBINE to form a “higher” entity type.
  - Determine primary key of new table
  - Amend old tables associated with the old key(s)

# Multi-Typing

- Generalisation leads to the creation of “higher” entity type(s).
- However these super-types contain many null data elements
- Multi-typing addresses this problem by creating super-types and sub-types.
- A sub-type can be thought of as an “instance” of the super-type, i.e. a way of categorising occurrences of the super\_type.
- A single occurrence of the super-type may be made up of one or more sub-types
- A sub-type cannot exist without the super-type.

# Multi-Typing ...

- Super-Type
  - PERSON(Person-ID, Person-Name, Person-Address, Person-Tel-No)
- Sub-Type
  - EMPLOYEE(Person-ID [EMPLOYEE], Employee-Appointed-Date, Employee-No)
- Sub-Type
  - STUDENT (Person-ID [STUDENT], Student-Enrolment-Date, Student-No)

# Benefits of Normalisation

- Data requirements are thoroughly analysed:
  - Data interdependence are recognised
  - Meaning and definition of each data element are established
  - Update anomalies are removed
  - Data inconsistencies are eliminated
- Simplified way of compiling data into a set of non-ambiguous entity types
- Practical approach built on theoretical basis
- Foundation for an optimum physical data base design using any DBMS
